When City College of San Francisco announced that it would be closing its Academic Support Center, a space for those in need of help with career development and academic planning, the announcement was met with mixed emotions. From the outside, the ASU may look like a small, out-of-the-way space in the heart of the campus. But those who used the center know what it meant to the students who relied on it. "One of the things that [a graduate student] would find here was that she would be matched with a professor who she could actually work with," said Student Association President Steve Chelini. "Instead of being a drop in the bucket for the school, it really brought all of the school together and all of the students who came here, not just those who came through the ASU, but all the students who came through the campus." Students were sad to see the ASU close, but many felt that the help it offered would be offered at a better location, given the large increase in enrollment. "We kind of just have to deal with it," said junior Michael Ewbank. "There are so many things that happen to us [as students] that are just out of our control." The closing of the center came on the heels of the closing of three other city college centers: The Educational Opportunity Center, the Minority Student Support Center, and the Women's Studies Center. Many students lamented the lack of coordinated services in the other centers, and were confused as to why only one would be closed. "It's really rare for a college to close four centers all at once," said Chelini. "And it seems like they're closing everything." The ASU was the only center that was primarily a reference point for students in need of extra help. When the other centers closed, they would often see their problems resolved by the campus-wide offices, rather than by a dedicated center. One of the problems was that the school's enrollment increased significantly since all the other centers closed. There were more students for the ASU to serve. "The ASU was a pretty unique place

A review of the change in population structure and distribution of *Allolobophora caliginosa* (Ciliophora: Oligohymenophorea) in Japan and its potential for genetic resource of the species. *Allolobophora caliginosa* (Hartmann-Schröder) Nägele is a major food source for mackerels, sardines and sprats, and is an indispensable part of the marine food web. The species has been used for food production and the preservation of wild resources due to its high ecological tolerance and strong resistance to unfavorable environmental conditions. However, little information is available regarding the change in its population structure and distribution in Japan and its potential for genetic resource of the species. The present review provides information on the historical records of *A. caliginosa* in Japan. To this end, the review provides a summary of the geographical distribution of *A. caliginosa* and its life stages in Japan, and a summary of its fishery data. Finally, the potential use of *A. caliginosa* as an index for monitoring the ecological effects of anthropogenic activities on the marine environment was discussed.

Functional end-to-end anastomosis of thin collagen tubes: an in vivo model of arterial bypass surgery. We have developed a functional end-to-end anastomosis between two thin collagen tubes that mimic, respectively, the left internal mammary artery and coronary artery. The functional aspect of this model resides in the observation of the appearance of a significant constriction of the anastomosed portion, a phenomenon that we observe in normal coronary bypass surgery. To achieve this result we have modified an original surgical technique in which a thin collagen tube, similar to a blood vessel and called anastomotic graft, is used to revascularize a coronary artery. This simple but efficient model was applied to study the appearance of atherosclerosis after coronary bypass surgery in Wistar rats ($n = 10$) and to test the effect of post-surgical medication on early atherosclerosis. We found that this model resulted in anastomoses that were patent and that were functionally similar to the in vivo normal bypass graft.
